Abstract Objective: To investigate the changes of serum interleukin-18 (IL-18) and tissue factor (TF) levels in patients with acute respiratory distress syndrome (ARDS) and their relationships with prognosis. Methods: Ninety-two patients were selected for the study, among them, there were 26 mild cases (mild group), 36 moderate cases (moderate group), and 30 severe cases (severe group). According to prognosis, patients were divided into survival group (50 cases) and death group (42 cases). Eighty healthy persons in the same period were selected as control group. Levels of serum IL-18 and TF were measured by enzyme-linked immunosorbent assay (ELISA). The changes of serum IL-18 and TF levels in each group and their clinical predictive values for the prognosis of ARDS patients were observed. Results: The levels of serum IL-18 and TF in ARDS group were significantly higher than those in control group (all $P<0.05$). Levels of serum IL-18 and TF in severe group and moderate group were significantly higher than those in mild group, and those in severe group were significantly higher than those in moderate group (all $P<0.05$). The levels of serum IL-18 and TF in the death group were significantly higher than those in the survival group (all $P<0.05$). ROC curve analysis showed that the AUC of IL-18 was 0.755, the truncation value was 110 pg/mL, the sensitivity was 75.00%, and the specificity was 81.67%; AUC of TF was 0.725, truncation value was 2.13 U/L, sensitivity was 65.00%, specificity was 76.67%. COX multivariate regression analysis showed that age, APACHEII score, serum IL-18 and TF were independent risk factors influencing the prognosis of ARDS patients (all $P<0.05$). Conclusion: Serum IL-18 and TF levels in patients with ARDS increase, which is related to the severity of the disease, and can be used as a prognostic indicator of ARDS patients.

讨论

炎症反应在 ARDS 发生发展中起关键作用,全身炎症反应聚集肺部,使炎性递质呈瀑布样释放,抗炎因子与促炎因子平衡失调,升高肺微血管通透性,引起肺水肿,形成透明膜及肺泡出血等病理变化,当病情发展到一定程度可导致肺纤维化,造成患者死亡^[5]。IL-18 是近年新发现的一种属于 IL-1 家族的重要促炎因子,与 IL-12 功能相似,由单核细胞、巨噬细胞及淋巴细胞等分泌。当发生炎症反应时,患者血清 IL-18 水平显著升高,与肺部炎症反应及肺纤维化形成紧密相关^[6]。柯耀棋等^[7]报道慢性阻塞性肺疾病患者血清 IL-18 水平升高,且急性加重期高于稳定期,证实 IL-18 参与气道炎症反应,与疾病严重程度相关。本文结果显示,ARDS 组患者血

清 IL-18 水平高于对照组 ($P < 0.05$),与袁雪丰等^[8]研究结果相似,提示 IL-18 在 ARDS 患者血清中高表达,可能参与其致病过程。

TF 又名凝血因子Ⅲ,是一种跨膜糖蛋白,为外源性凝血途径关键起始因子,与血液循环和血管壁状态相关。正常生理状态下,TF 仅在血管外细胞表达,当血管内皮受各种刺激发生损伤时,血管内皮细胞及机体多种正常细胞均可分泌 TF,在血液中,TF 与凝血酶原Ⅶ结合后形成活化凝血因子Ⅶa (FⅦa),进而结合成 TF-FⅦa 复合物,激活 FX,形成凝血酶并放大,导致纤维蛋白沉淀,活化血小板,启动凝血途径^[9]。张春玲等^[10]报道 TF 在肺栓塞大鼠肺组织中高表达,并随栓塞时间加长而升高,与本研究结果相似。

本研究显示,重度组及中度组患者血清 IL-18 及 TF 水平高于轻度组,且重度组高于中度组 (均 $P < 0.05$),提示血清 IL-18 及 TF 可能参与 ARDS 发生发展,且与疾病严重程度相关,病情越严重,血清 IL-18 及 TF 水平越高。进一步研究分析显示,死亡组患者血清 IL-18、TF 水平明显高于存活组,与 Makabe 等^[11]研究结果相似,提示血清 IL-18、TF 水平可能与 ARDS 患者预后不良有关。ROC 曲线分析显示,IL-18 预测 ARDS 的 AUC 为 0.755,截断值为 110 pg/mL,敏感性为 75.00%,特异性为 81.67%;TF 的 AUC 为 0.725,截断值为 2.13 U/L,敏感性为 65.00%,特异性为 76.67%,与 Borthwick 等^[12]研究结果相似。最后经 COX 多因素分析显示,年龄、APACHE II 评分、血清 IL-18、TF 是影响 ARDS 患者预后的独立危险因素,提示年龄大、APACHE II 评分高、血清 IL-18 及 TF 水平高,患者死亡风险增高。

可使肾小管上皮细胞停留在 G1 期加重肾损害。高 IGFBP-7 水平反应了更加严重的肾损伤^[16]。IGFBP-7 的下调可以减轻炎症反应,从而降低 HMBG1 水平。动物实验研究发现 HMBG1 或促进缺氧-复氧介导的肾小管上皮细胞凋亡^[17]。这说明乌司他丁可通过直接作用于多种水解酶减少炎症反应,也可直接间接降低尿 IGFBP-7 和 HMGB1 水平,从而保护肾脏细胞,对 AKI 具有更好的疗效。

综上所述,乌司他丁对脓毒症 AKI 的肾功能具有保护作用,可降低炎症因子,这可能与乌司他丁可降低尿 IGFBP-7 和 HMGB1 的水平有关。
